摘要

It often occurs that plants have unusually withered in planting projects, but there has never been any study conducted based on what actually has happened. This study tries to investigate those planting problems occurred in landscape architecture. The study first makes a statistics of the problems actually happened in planting projects and then explores the causes for the problems encountered in the various stages of those planting projects. The improving strategies for those problems encountered are proposed through expert interviews. Finally, based on the problems encountered, a self-check list is developed. The Delphi method is used to validate the self-check list.
